### CEE 4674 Airport Planning and Design

### Geometric Design: Part 2 Runway Exit Design and Exit Locations

#### Dr. Antonio A. Trani Professor of Civil Engineering Virginia Polytechnic Institute and State University

Blacksburg, Virginia

Geometric Design of Runway Exits

Sources of information:

- FAA AC 150/5300-13B (Chapter 4)
  - Sections 4.8.2 through 4.8.6
- ICAO Aerodrome Manual Volumes 1 and 2

Design principles:

- Provide ample space for aircraft to maneuver out of the runway
- Locate runway exits consistent with aircraft landing performance

# Important Issues about Runway Exits

- Runway exits are responsible for making operations more efficient on the ground
- Poorly designed runway exits add valuable service time (i.e., runway occupancy time)
- Poorly placed runway exits can contribute to go-arounds and runway incursions
- Runway occupancy time and its standard deviation are critical parameters for runway capacity estimation

# Runway Occupancy Time

- The time elapsed between the aircraft crossing the runway threshold and the time when the same aircraft crosses the imaginary plane of a runway exit paved area (aircraft wingtip or tailtip)
- Issues about ROT
  - The definition of ROT has been used inconsistently throughout the years
  - Many early ROT studies failed to recognize that when an aircraft starts turning towards the runway exit, the aircraft is still using the runway until its wingtip clears the runway edge plane

# Factors Affecting Runway Occupancy Time

- Aircraft type (AAC group)
- Runway geometric design factors
  - Runway width
  - Pavement condition (wet, dry, contaminated)
- Taxiway geometry design factors
  - Number of runway exits on the runway
  - Taxiway type
  - Taxiway network interaction
- Pilot technique
- Traffic pressure (i.e., having another aircraft on short final behind)
- Gate location

**Wirgi**

# Runway Exit Design

## Geometric Design Standards for Runway Exits Sources:

- FAA AC 5300-13B (Chapter 4)
  - Sections 4.8.2 through 4.8.6
- ICAO Aerodrome Manual Volumes 1 and 2 Design principle:
- Provide ample space for aircraft to maneuver out of the runway
- Make the runway exits easily identifiable and usable

# What is the Issue with Runway Exits?

- Runway exits are responsible for making operations more efficient on the ground
- Poorly designed runway exits add valuable service time (i.e., runway occupancy time)
- Poorly placed runway exits can contribute to goarounds and runway incursions
- Runway occupancy time and its standard deviation are critical parameters for runway capacity estimation

# Definitions

# • Runway Occupancy Time (ROT)

—The time elapsed between an aircraft crossing the runway threshold and the time when the same aircraft crosses the imaginary plane of a runway exit paved area

## Issues about ROT

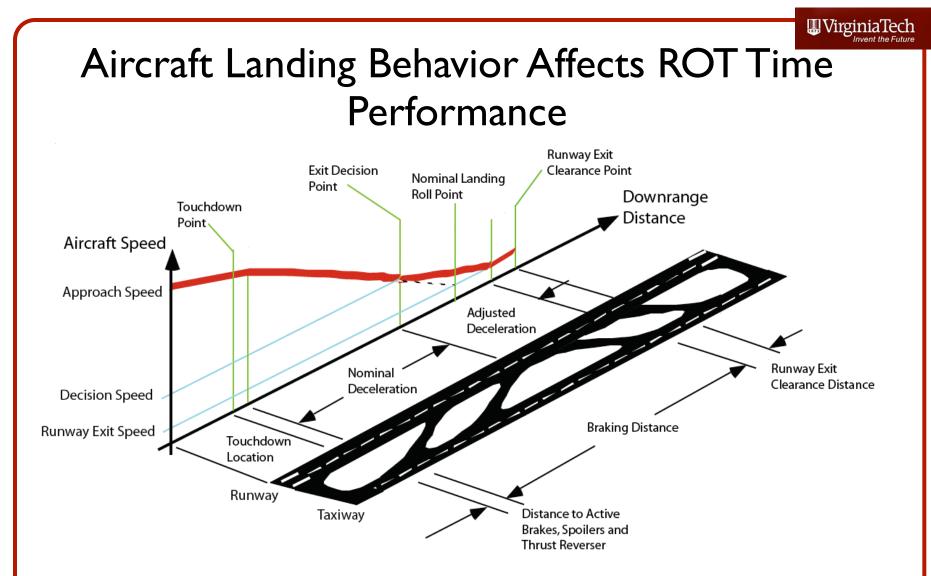

—The definition of ROT has been used inconsistently throughout the years

—Many early ROT studies failed to recognize that when an aircraft starts turning towards the runway exit, the aircraft is still using the runway until its wingtip clears the runway edge plane

# Factors Affecting ROT

- Aircraft mix
  - Percent of aircraft in various runway performance groups
- Runway and runway exit geometric design factors
  - Runway width
  - Pavement condition (wet, dry, contaminated)
- Taxiway geometry design factors
  - Number of runway exits within the aircraft mix acceptability requirements
  - Taxiway type
  - Taxiway network interaction
- Pilot technique
  - Traffic pressure (i.e., having another aircraft on short final behind)
  - Gate location
  - Airport familiarity

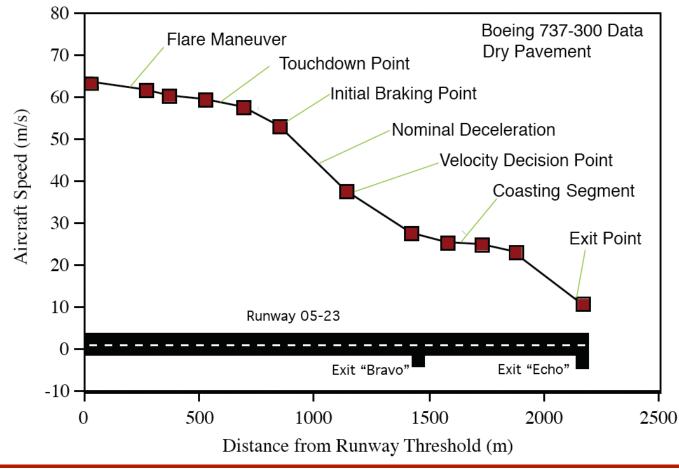

🎹 Virginia

For hand calculation analysis of runway exit placement, we can model the landing roll into three segments: air segment, free roll segment, and deceleration segment

# Aircraft Landing Roll Profile

 Sample data collected at Charlotte-Douglas International Airport (CLT) Runway 05-23 (Trani et al., 1996)

Airport Planning and Design (Antonio A. Trani)

# **Typical Landing Milestones**

Air phase starts Crosses the runway threshold Reference speed over threshold (Vref)

Air phase ends Main gear touchdown Typically 95% of threshold crossing speed

Deceleration phase starts Nose gear touchdown Engine thrusts reversers deployed Wing spoilers deployed Wheel braking on

# Typical Landing Milestones (2)

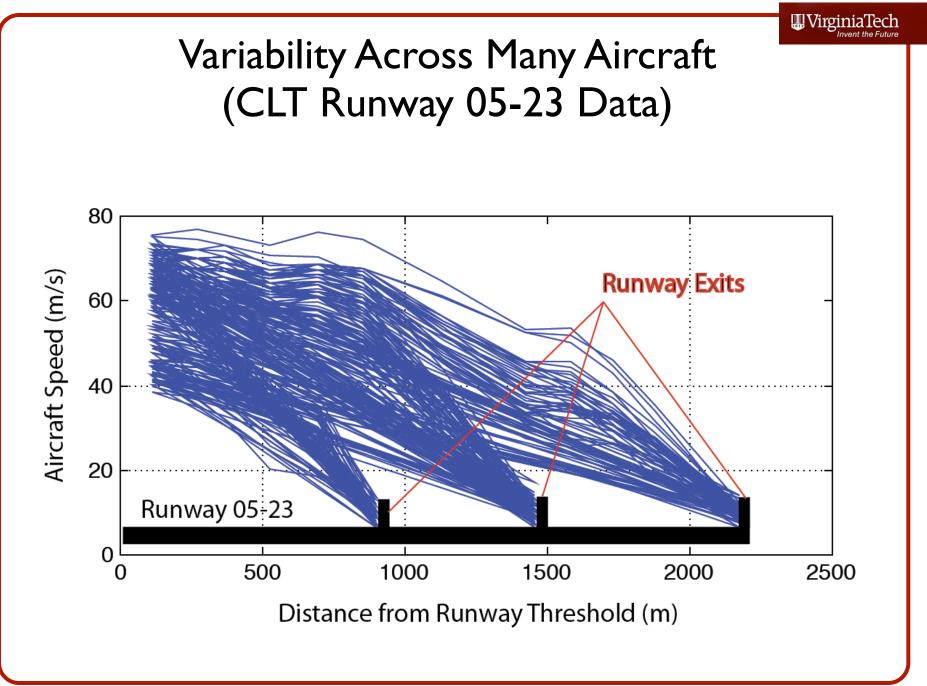

Landing deceleration segment Engine thrusts reversers deployed Wing spoilers deployed Wheel braking on

Turnoff maneuver Engine thrusts reversers stowed Wing spoilers retracted No wheel braking

Most jet powered aircraft manufacturers recommend thrust reversers to be stowed at 60 knots to avoid engine foreign object ingestion

# Effects of ROT on Runway Capacity

- Modest gains in runway saturation capacity are possible with reductions in ROT because in today's environment, inter-arrival separations dominate over runway capacity
- ROT nevertheless is important in runways used with mixed operations (i.e., arrivals and departures) in both IMC and VMC conditions
  - Reduced weighted average ROT values reduce the gap needed to launch departures between successive arrivals
  - The same effect is true if reductions in the standard deviation of ROT are possible
- ROT is more important under VMC operations because inter-arrival times (IAT) are smaller compared to those observed during IMC conditions
- Standard deviation of ROT is very important
- Some small gains under IMC conditions (mixed operations in a single runway)

# Runway Exits

- The purpose of runway exists is to improve service
- times of airport runways
- The number of runway exists varies from airport to
- airport and within runways at the same airport
- Several types of runway exits can be

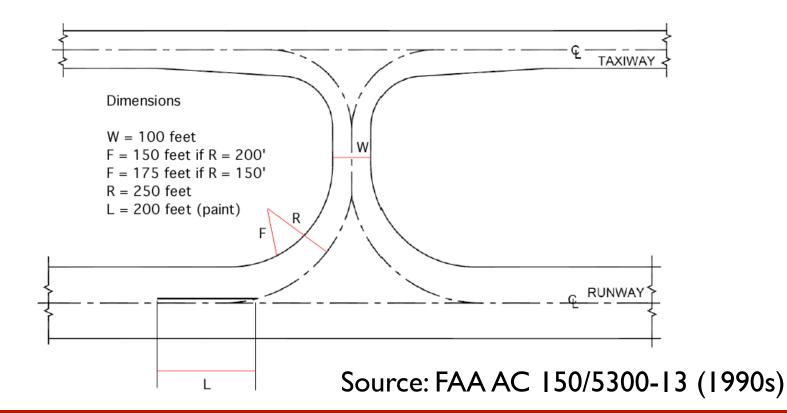

# Types of Runway Exits

Runway Exit Type	Characteristics and Use	Remarks and Exit Speeds
Right-angle	Low volume of traffic	Low speed
(90 degree)	Ends of a runway	(5-8 m/s)
45 degree General Aviation	Old design (not recommended)	Medium speeds (8-15 m/s)
30-degree Constant	Two versions	High-speed
Radius Design	Use when > 30 operations/hr	15-23 m/s
30-degree Spiral Design	Adopted in the mid 80s	Transition spiral
	Use when > 30 operations/hr	15-23 m/s

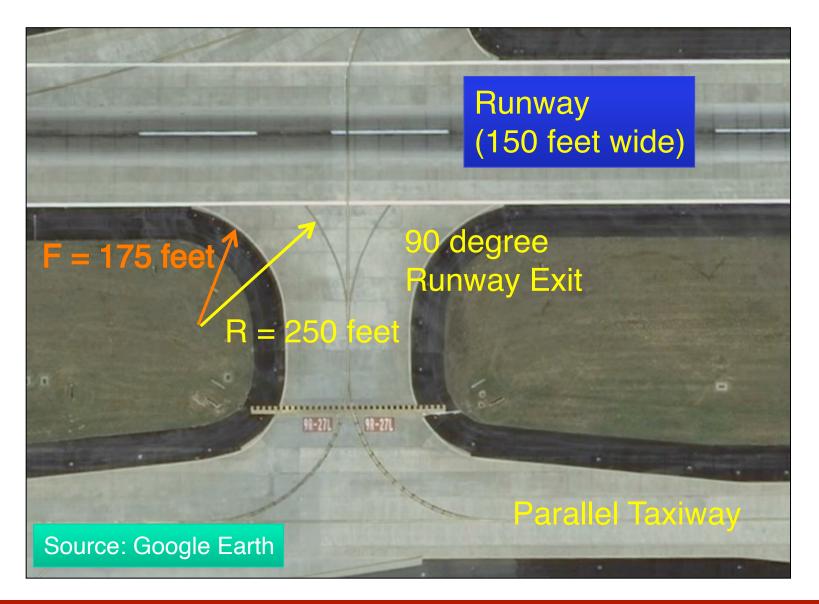

UirginiaTech

# **Right-Angle Exits**

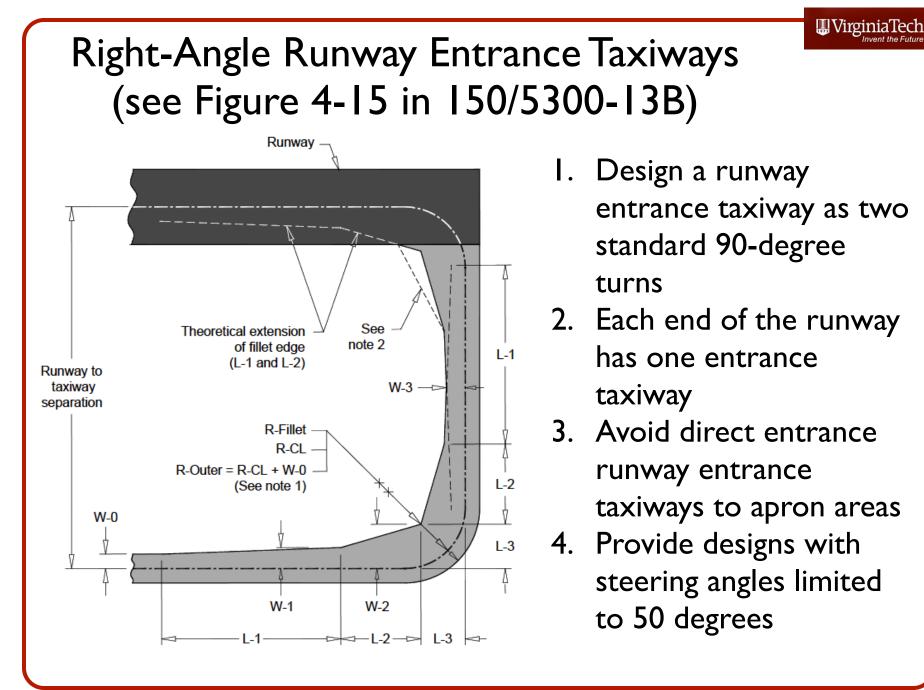

- Old (legacy) design baseline centerline radius was 250 feet
- Pavement edge radius varies according to runway width
- Legacy design has been replaced by new design practice

#### Sample Implementation (ATL)

UirginiaTech

# Right-Angle Runway Entrance Taxiway Dimensions when steering angles > 50

UirginiaTech

nvent the Future

Airport Planning and Design (Antonio A. Trani)

# Right Angle Runway Exit (see Figure 4-19)

New standard for right angle exits Build the exit as a projection of two runway entrance exits

## **Example Problem**

- Design a new right-angle runway exit for a 8,000 foot runway (150 foot wide)
- Critical aircraft design is the Airbus A340-600
- For this airport the runway to taxiway centerline is 500 feet

# Procedure

#### Step I - Identify the Airbus A340-600 as TDG-6

CMG = 121.6 feet MGW = 41.37 feet

#### Step 2

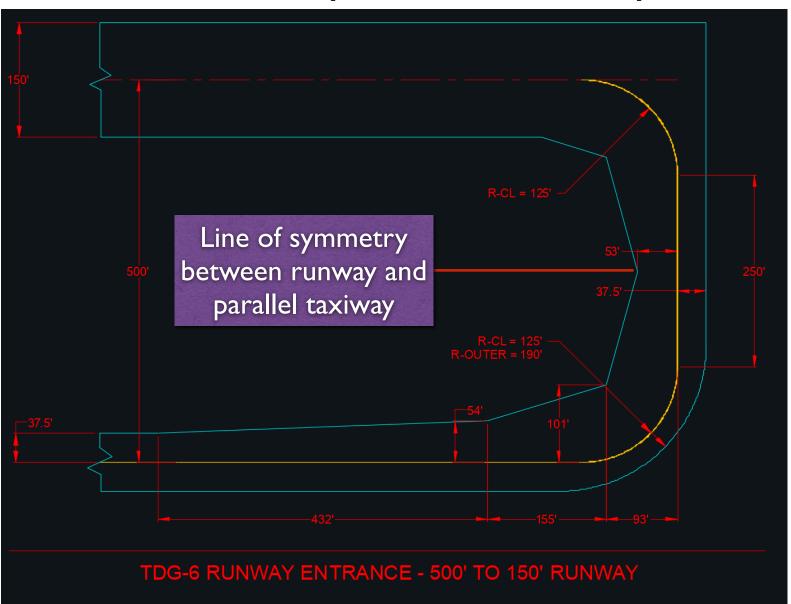

- Use the FAA Taxiway Fillet Design Tool or tables in Appendix J of the Faa AC 150/5300-13B
- If the steering angle estimated by the fillet design tool exceeds 50 degrees, increase R-CI and fillet dimensions according to Table 4-4

#### Step 3

• Draw the solution using CAD software

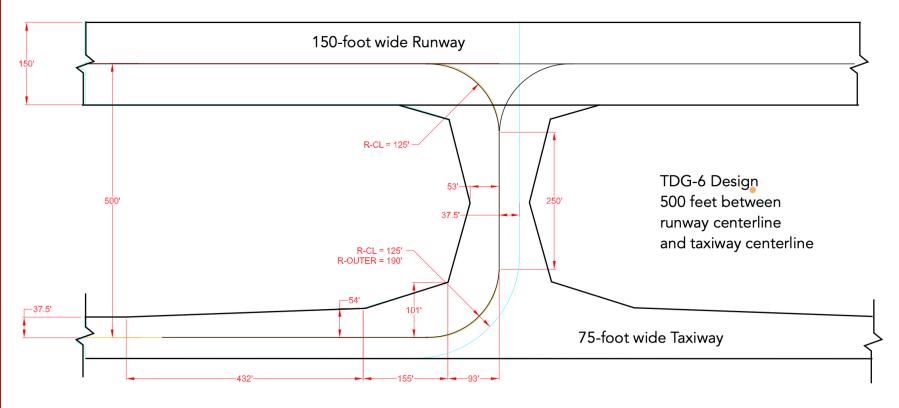

🋄 Virginia

#### TDG-6 Runway Entrance Taxiways

UrginiaTech

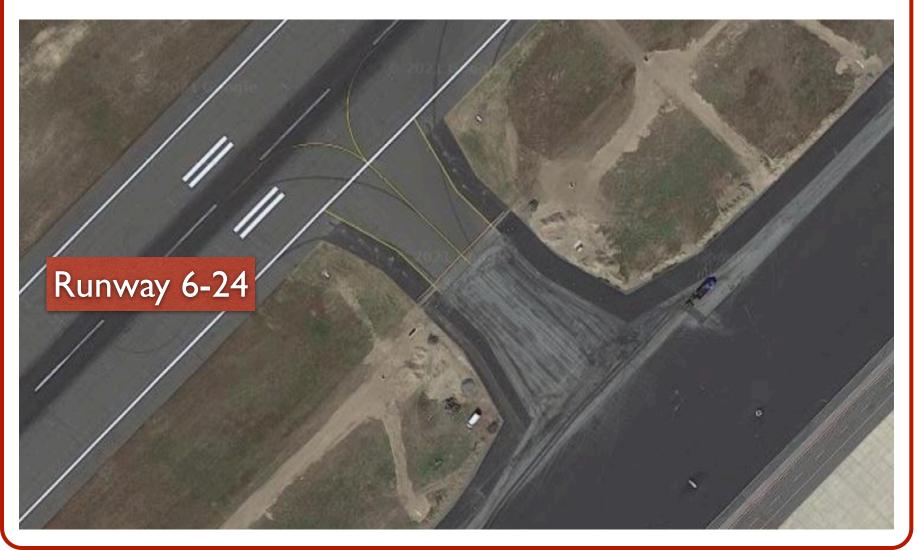

# Right Angle Runway Exit (TDG-6 Group) Solution

Build the runway exit as a projection of a runway entrance exit with two sides

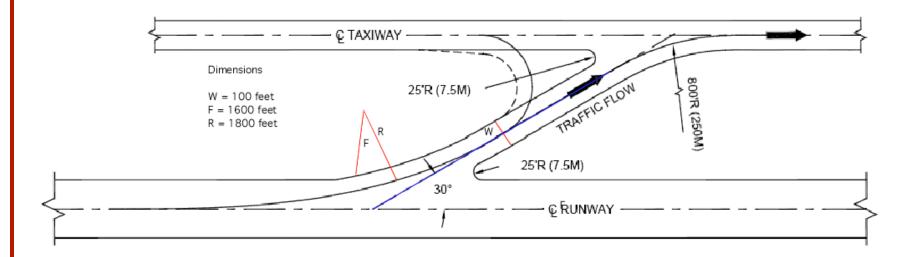

### Sample Implementation of a Right Angle Runway Exit (Bradley Intl.Airport)

# Acute Angle Runway Exits Also Called High Speed Runway Exits

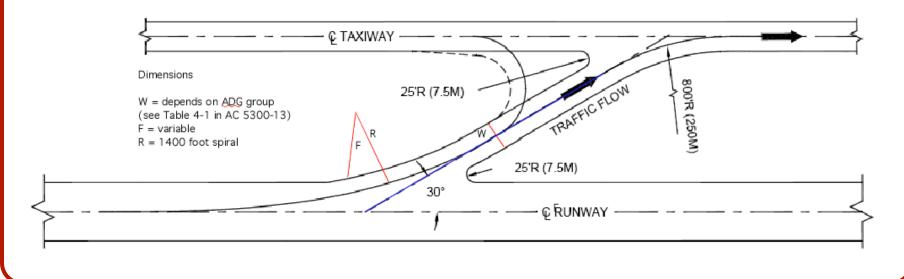

# Acute Angle or High-Speed Runway Exit 30 Degree - Constant Radius (**Old Standard** with 1800 foot centerline radius)

Research done in 1960s by Horonjeff demonstrated that a 1,800 foot radius would allow aircraft to exit at 60 knots.

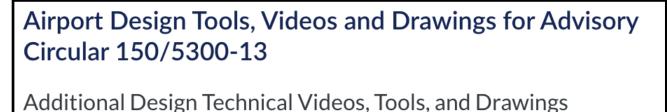

### Acute Angle or High-Speed Runway Exit 30 Degree - Spiral Design (Another Legacy High-Speed Runway Exit Design)

- Nominal 1400 feet centerline spiral
- FAA computer program AD42.exe application for design (companion computer program to AC 5300-13)

HIGH-SPEED EXIT FOR TDG-6 - 500' TO 150' RUNWAY

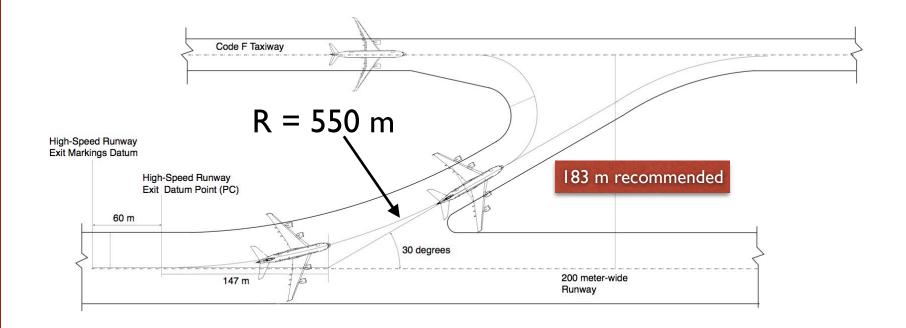

Drawings available at: <u>https://www.faa.gov/airports/</u> <u>engineering/airport\_design</u>

#### Comparison Between HS Exit Designs

- The old 30-degree acute angle exit standard was originally proposed by Horonjeff et al. with a constant centerline radius of 1800 feet
- In the early 1990s, a 1400 foot spiral transition was introduced as the 30 degree (acute angle) design
- In 2013, the FAA went back to a constant radius design (1500 feet at centerline)
- Note that in the current designs suggested by FAA, the transition centerline radii dimensions change at the junction with the parallel taxiway for various TDG groups

### ICAO Rapid Exit Taxiways

- ICAO uses a constant radius 550 meter curve
- The ICAO standard is similar to the old FAA standard (first developed by Horonjeff in 1961)

# Design and Operational Considerations

- Virginia Tech observations suggest that most HS exits are used 10-20 knots below their design speed (60 knots)
- Perhaps this could be one reason for the FAA to change course
- However, Virginia Tech research suggest that pilots do not like abrupt transitions from a 150 foot runway width to a narrow 75 foot HS runway exit (as is the case for the current FAA design)
- Always be generous with the transition form a wide runway to a narrow runway exit
- HS runway exits are more effective when the separation between the runway and the parallel taxiway is at least 600 feet

#### To be Effective High-Speed Runway Exits require Good Separation Between Runway and Parallel Taxiway

Table 4-5. Runway to Taxiway Separation for Reverse Turns from a High-Speed Exit Based on TDG

Runway Centerline to	TDG									
Taxiway/ Taxilane Centerline	3	4	5	6						
Recommended separation	350 ft	450 ft	450 ft	600 ft						
	(107 m)	(137 m)	(137 m)	(183 m)						
Radius for 150-degree	79 ft	121 ft	121 ft	152 ft						
turn after 30-degree exit	(24.1 m)	(37 m)	(37 m)	(46 m)						
Minimum separation <sup>1</sup>	348 ft	427 ft	427 ft	485 ft						
	(106 m)	(130 m)	(130 m)	(148 m)						

Note 1: Minimum separation distance based on the standard 30-degree high speed exit and maximum 50degree steering angle for the reverse turn.

Source: Table 4-5 FAA AC 150/5300-13B

#### Example of a HS Runway Exit with 400 feet Separation (not recommended)

- Little tangent section on the HS exit for deceleration
- Taxiway is too close to the runway (pilots will exit at lower speeds)

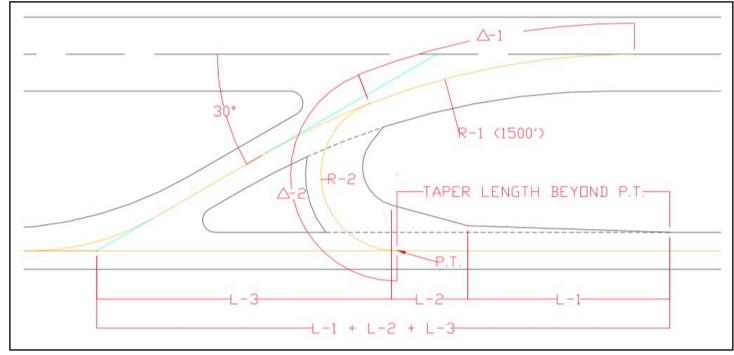

#### Example of a HS Runway Exit with 600 feet Separation (good practice)

- A generous tangent section on the HS exit for deceleration
- Pilots will exit at higher speeds in such design

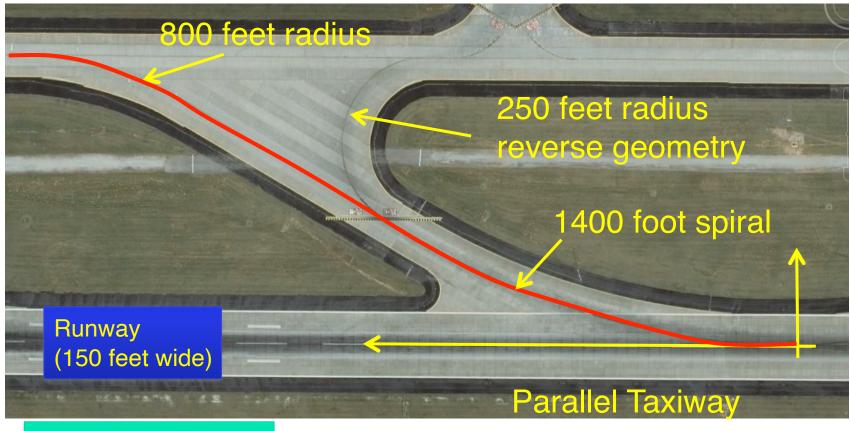

# FAA Spreadsheet Calculator for Runway Exit Design

 https://www.faa.gov/airports/engineering/ airport\_design/ **Wirginia** 

#### UirginiaTech

# Example Implementation (ATL) 30 Degree Angle Runway Exit

Source: Google Earth

# High-Speed Speed Exits (IAD) (Standard 30 degree angle)

#### No longer recommended Large pavement overlap can confuse pilots

Airport Planning and Design (Antonio A. Trani)

#### Issues with 30 Degree Runway Exits

- The FAA recommends a minimum runway-taxiway separation of 600 feet for High-Speed runway exits
- Some airport have used 30 degree runway exits with only 400 feet between runway and taxiway centerlines (avoid this is bad practice)
  - The result is low exits speeds and possible issues with busting hold lines
- Be careful and try to provide the minimum 600 foot recommended distance
- Consider limited pilot visibility while crossing active runways

## FAA Airport Design Website

 Available at: <u>https://www.faa.gov/airports/</u> <u>engineering/airport\_design/</u>

#### Available tools:

# Example of Limited Visibility from Aircraft Cockpit Driven by Hold Line Location

• Before the aircraft nose reaches the hold line, the aircraft wingtip violates the hold line distance

# Runway Exit Placement

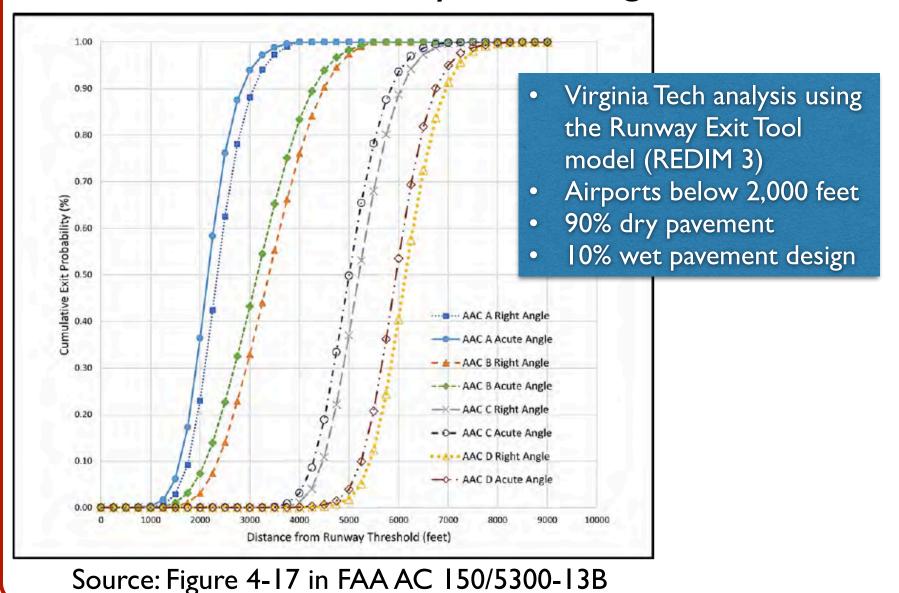

#### Procedures to Locate Runway Exits

- Factors that affect the runway exit locations:
  - Fleet mix
  - Operations/hr
  - Environmental conditions (wet vs. dry pavement)
  - Terminal or gate locations
  - Type and number of runway exits
- Manual tables developed by ICAO and FAA
- Use computer models like REDIM Runway Exit Design Interactive Model (Developed at Virginia Tech for the FAA and NASA)

#### Methods to Locate Runway Exits

- Graphical solution of cumulative exit probability runway exit use charts (see Figure 4-17 in AC 150 5300-13B)
- Three segment method using simple aircraft kinematics
- Use the Runway Exit Design Tool (REDIM version
   3) developed by Virginia Tech for the FAA

**Air Transportation Systems Laboratory** 

### Runway Exit Location Example Problem Using Cumulative Runway Exit Design Curves

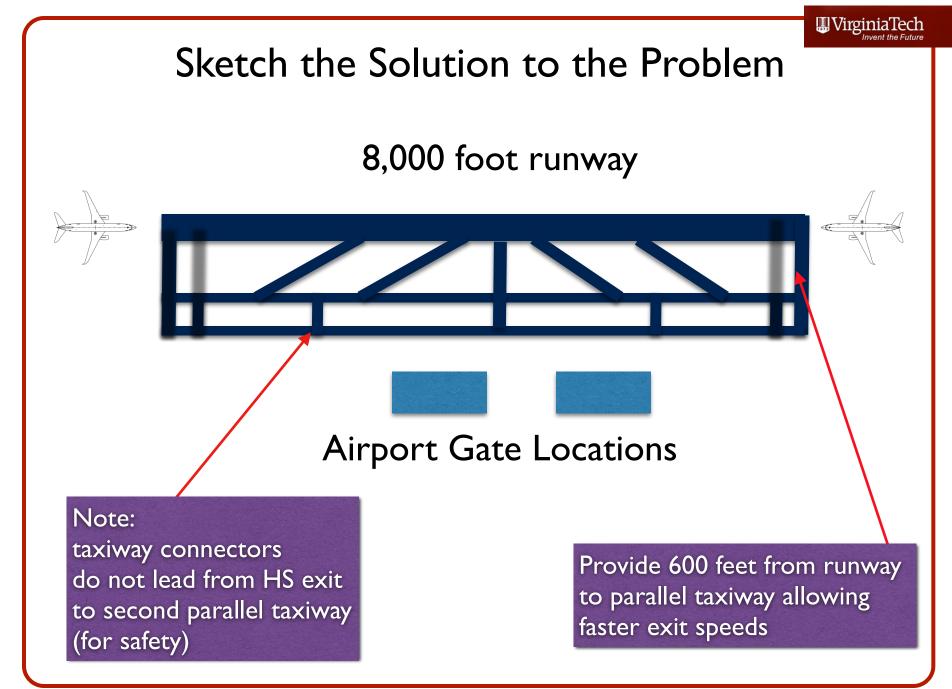

### Aircraft and Airport Environment

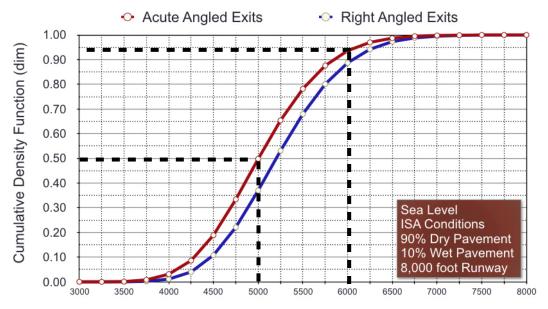

- Airport located at sea level conditions
- 8000-foot runway
- Minimum of 4 runway exits are desired
- AAC groups
  - B 20% of fleet mix
  - C 80% of fleet mix
- More than 30 operations per hour in the peak period

### Typical Questions and Workflow

- Locate two high-speed (acute angle) runway exits per direction to accommodate 50% and 95% of AAC C class aircraft
- Sketch a runway exit solution
- Measure ROT using the FAA/Virginia Tech Runway Exit Design Model (REDIM)

### Evaluate Runway Exit Usage at Desired Locations Solution to the Problem

Location of Runway Exit (feet)

### AAC C Class Aircraft

Location of Two High-Speed Exits Ist - 5,000 feet (50%) 2nd - 6,000 feet (95%) Always use 800 feet as the minimum distance between high-speed runway exits

The criteria is satisfied (1,000 feet between two HS exits)

# General Information About the Model

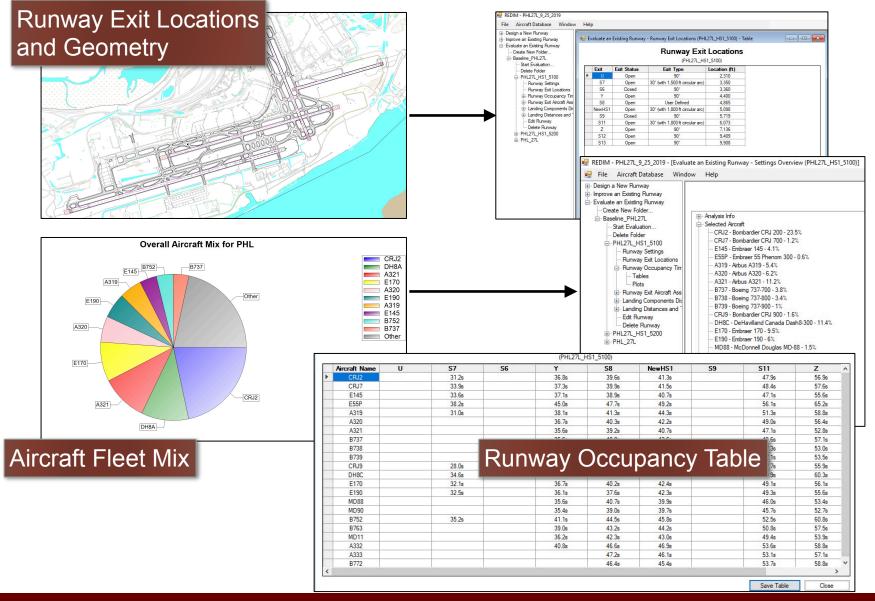

- Model has three analysis modules:
  - a) Evaluation of an existing runway
  - b) Improvements to an existing runway
  - c) Design optimal locations for a new runway

Model uses Monte Carlo Simulation to predict aircraft landing roll performance

- Stand-alone Windows
   application
- Requires ~1.8 Gb of hard disk space
- New runway clustering
- Improvements to landing roll profile calculations

### **Differences with Previous Runway Exit Model**

UirginiaTech

Item	Older Model (REDIM 2.1)	New Model (REDIM 3)		
Wind information	Single wind speed and direction	Landing observations are effected by local wind conditions		
	Airports have complex wind patterns	Landing events database has wind speed and direction for each landing		
		REDIM 3 designs for average wind conditions included in the landing speed distributions collected at 37 ASDE-X airports		
Runway gradient	Ten values of local gradients along the runway Model will calculate the average gradient and apply a very small correction factor	Runways designed for commercial operations have limited gradients by regulation (0.8% in first quarter of runway and a maximum of 1.5%)		
	apply a very small concetion factor	The correction factor for such runways is very small		
<b>D</b> ( 1'4'		We plan to investigate this issue in the future		
<b>Pavement conditions</b>	50/50 wet dry default condition	10/90 default condition in new model		
	Wet pavement conditions reduce nominal deceleration	Rainfall data collected at selected airports provided the basis for the new default		
		Wet pavement conditions reduce nominal deceleration		
Safety factor	Turnoff safety factor (user defined)	The new model is based on extensive runway and runway exit data		
		Observed runway exit speeds in the new model make the use of a safety factor in the turning maneuver unnecessary		
Aircraft fleet	5 aircraft modeled directly (Douglas DC9-30,	298 aircraft modeled		
	McDonnell Douglas MD-80, Boeing 727-200, Boeing 737-300 and Boeing 757-200)	Aircraft performance adjusted for airport elevation and temperature		
	70+ aircraft modeled indirectly based on landing distance parameters adjusted for airport elevation	Landing roll distributions use Kernel Density Functions (KDE) for individual aircraft (functions of runway length and runway exit types)		
	Aircraft performance adjusted for airport elevation and temperature	Model defaults to Aircraft Approach Group (AAC) category if a Kernel distribution does not exists for the aircraft in question		
	Model assumed all landing roll distributions to be normally distributed truncated to 2.5 sigma			

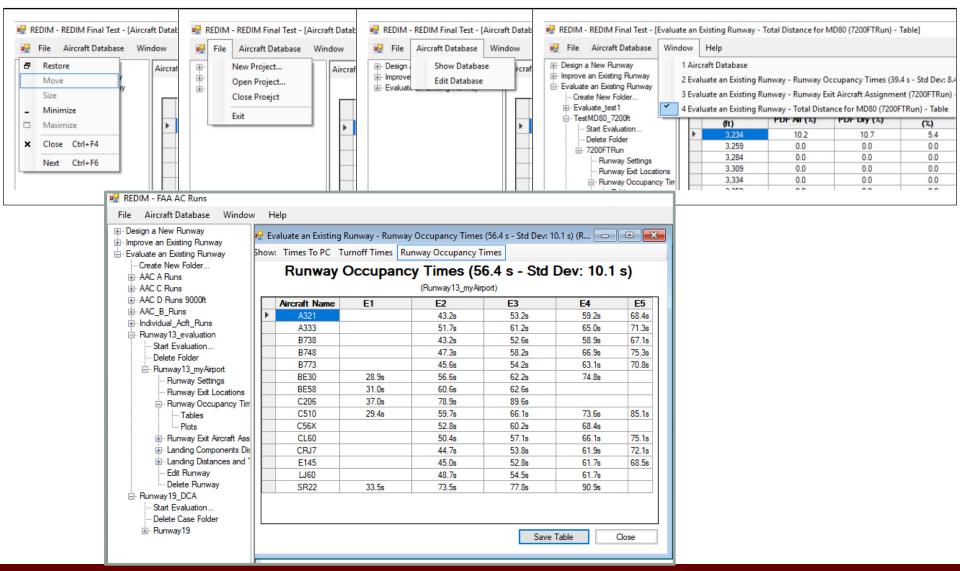

# Runway Exit Model 4 : Aircraft Database

- 330 aircraft modeled (directly or indirectly)
- Improved database consistent with the updated FAA Aircraft Characteristics Database (ACD)
- Includes the latest generation of aircraft (Airbus 220-300, A320neo, Boeing 737-8Max, etc.)

Runway Exit Model 4 Improvements: Runway Exit Data Handling

REDIM offers default runway exits

irginiaTech

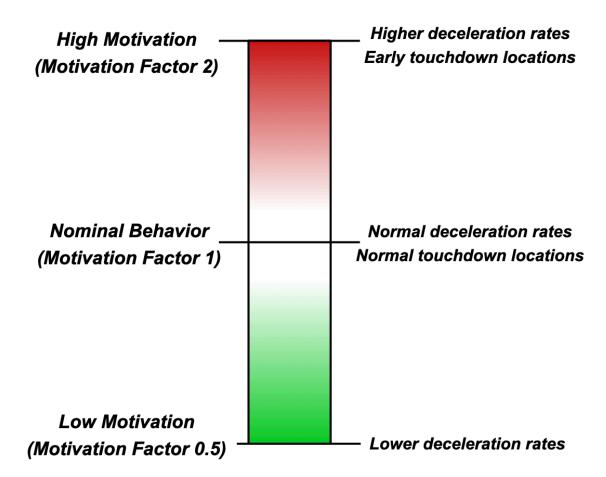

- REDIM offers a detailed procedure to define custom runway exits using relative(x-y) or absolute coordinates (latitudelongitude)
- REDIM 4 can store runway exits in a runway exit database file

# **Pilot Motivation Factor**

- We developed methods to characterize pilot motivation through statistical analyses of individual aircraft data
  - Deceleration rates
  - Touchdown distances
- Briefed a group of pilots invited by the FAA to understand factors that lead to pilot motivation
- All motivation factors provided in the model are within the kinematic capabilities of each aircraft

### Motivation Factor in the REDIM 4 Model Interface

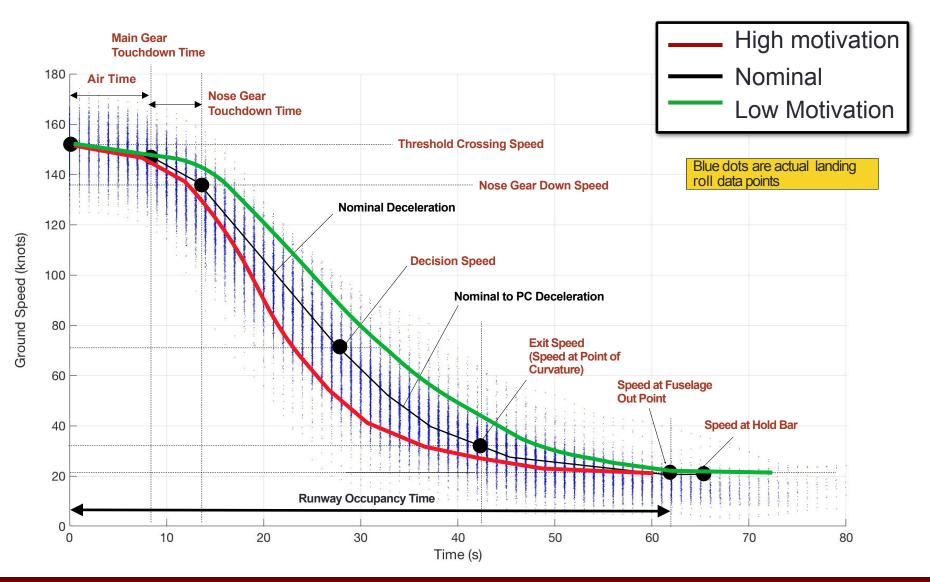

Evaluate an Existing Runway - Step 2 - Define Aircraft Mix for New Runway

Aircraft ID	Aircraft Name	Aircraft Design ▲ Group	Aircraft Approach Category	Aircraft Mix (%)	Motivation Factor	^
AT76	Aeropatiale ATR-72-600	III	В		1

During the landing simulation, Boeing 737-700 will use a motivation factor of 2.0 (high motivation)

# Landing Roll Profiles versus Pilot Motivation

Air Transportation Systems Laboratory

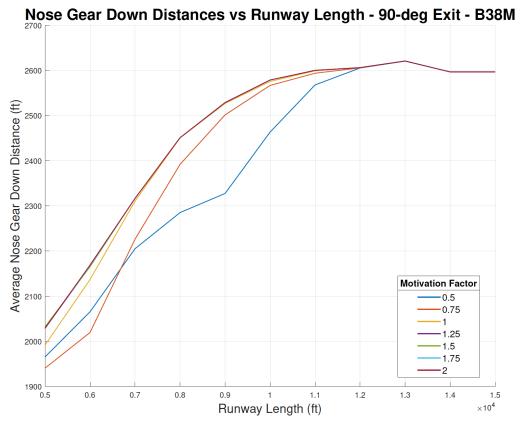

# Pilot Motivation in the REDIM 4 Model Starts with Modified Touchdown Locations

 The natural trend of touchdown locations is built into the model based on actual data

inia'l'ech

- Short runways produce early touchdown locations
- High motivation factors above 1.5 may reduce the touchdown location by 120-150 feet (~4.8%) on a 8,000-foot runway

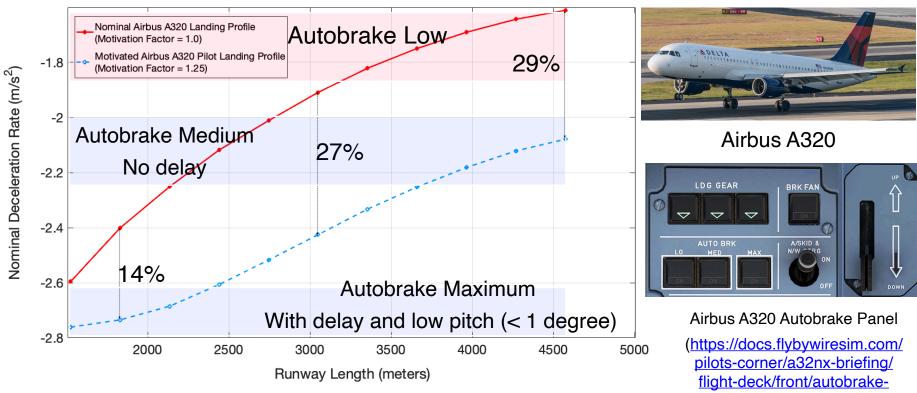

### Pilot Motivation Factor Effect on Nominal Deceleration Rate Spread Between MF 1 and MF 1.25 Averages 20% for Runways Up to 3,050 meters (10,000 feet)

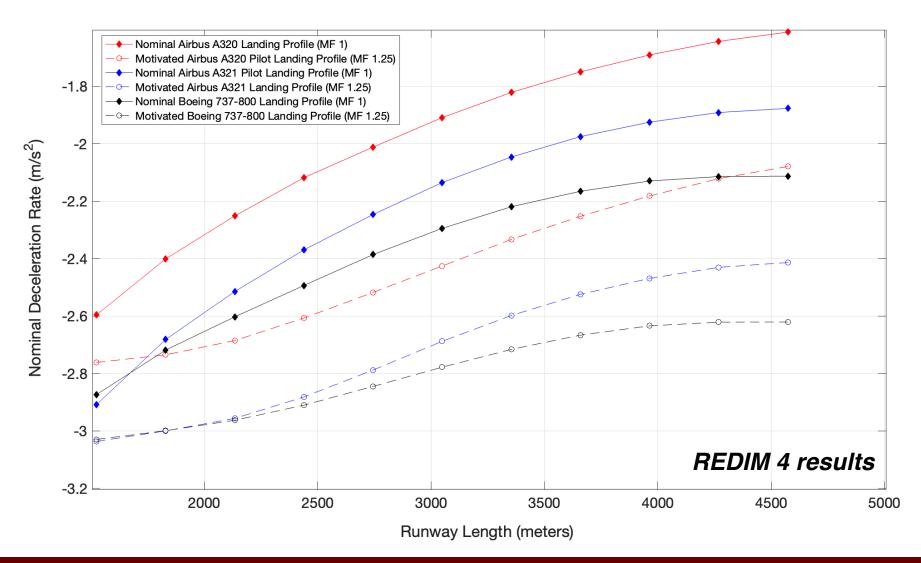

<u>gear/</u>)

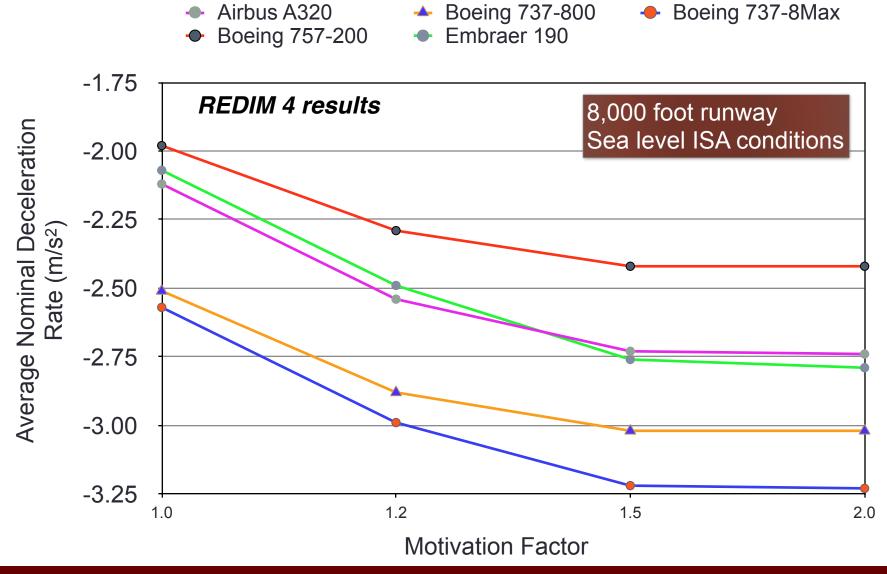

### Nominal Deceleration Rate and Pilot Motivation Factor

irginiaTech

Air Transportation Systems Laboratory

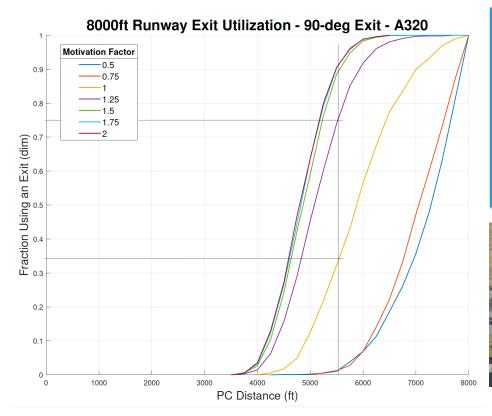

Air Transportation Systems Laboratory

Practical Implications of Changing the Pilot Motivation Factor on a 2,440-meter (8,000 feet) Runway

Increasing the pilot motivation factor from 1.0 to 1.25 doubles the cumulative runway exit probability of right-angle exits at a location 5,500 feet along the runway.

Airbus A320

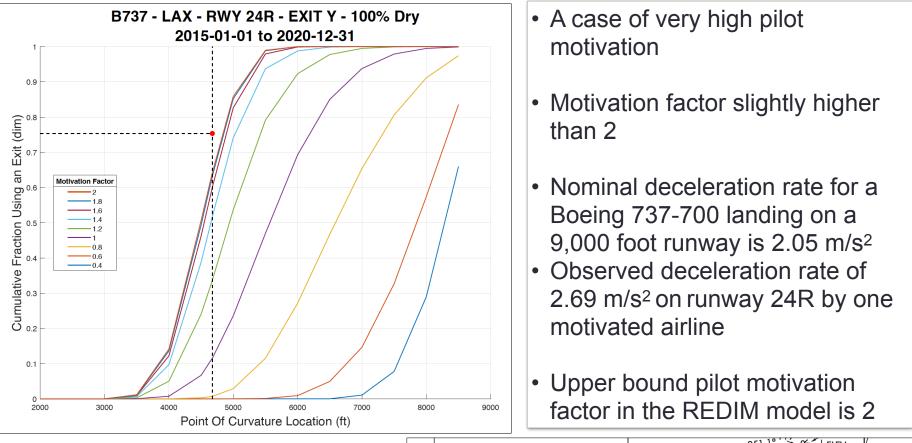

### **Example Motivation Factors at Selected Airports**

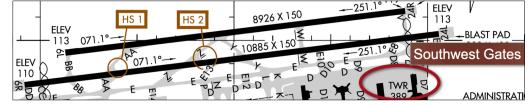

- Practical examples of how to translate motivation factor (MF) to real-world landing performance
  - Los Angeles Runway 24R
  - LaGuardia Runway 31
- REDIM model motivation factor guidance for model users

### 77.5% of Motivated Pilots of Boeing 737-700 Landings Exit at Yankee (Y)

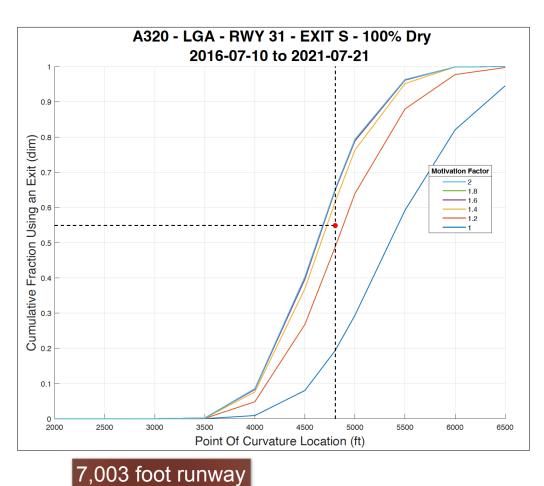

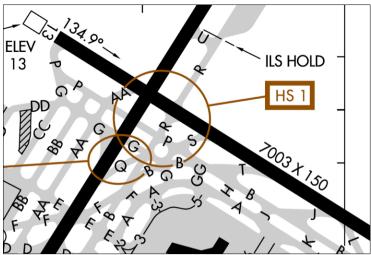

### 55% of Airbus A320 Landings at LGA Runway 31 Use Exit Sierra (S)

2017-2020 Data

- A case of higher than nominal pilot motivation
- Pilots are motivated is to avoid crossing runway 4/22 while landing on runway 31
- Observed motivation factor is ~1.25

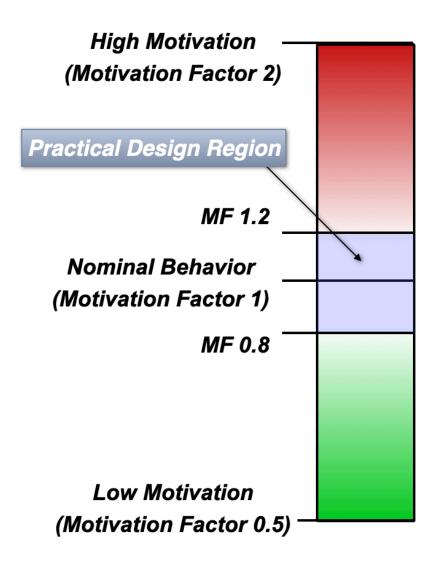

## **Recommended Guidance for Motivation Factors**

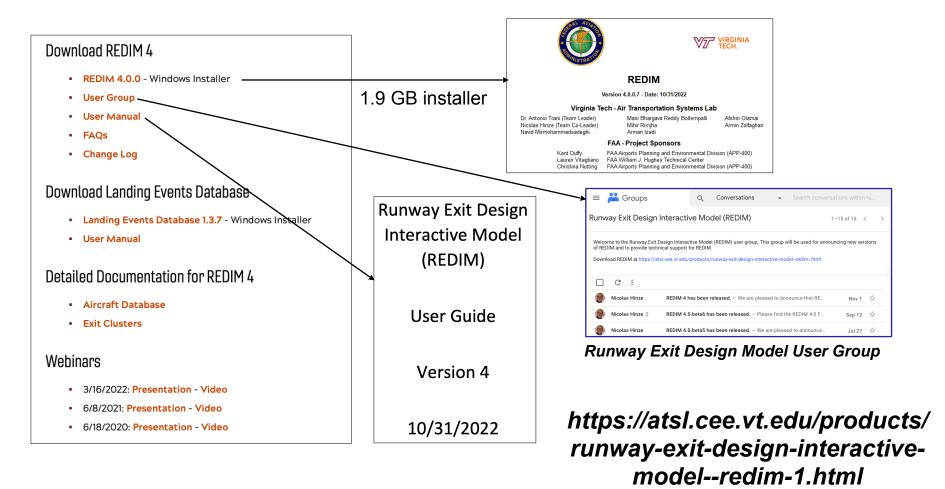

- REDIM 4 is designed to predict nominal landing roll behavior on a runway with a motivation factor MF 1.0
- High motivation factors are observed at some U.S. airports (MF 1.25 or higher)
- Practical design guidance should limit the placement of runway exits using MF factors between 0.8 and 1.2 to avoid high deceleration rates that may not be desirable in real-world commercial operations
  - Higher maintenance costs due to heavy braking
  - Passenger comfort
- For narrow-body aircraft, a motivation factor of 1.2 translates into 15-20% increase in deceleration rates compared to the nominal landing conditions

#### **Runway Exit Design Tool (REDIM Model) Resources**

# Example Use of the REDIM Model Runway Evaluation

# WirginiaTech

# Runway Evaluation Scenario: Fleet Mix

Aircraft	Fleet Mix (%)	Picture
Cirrus SR22	10	N874DC
Cessna Latitude (C680A)	10	
Airbus A320	25	DESTR.
Boeing 737-800	35	
Boeing 787-8	20	

# Runway Evaluation Scenario: Runway Exits

Runway Exit	Location (feet)	Exit Type		
Alpha	1500	Right-angle		
Bravo	3000	Right-angle		
Charlie	5000	Acute-angle (R-CL 1500 feet)		
Delta	6200	Acute-angle (R-CL 1500 feet)		
Echo	8000	Right-angle		
Foxtrot	8900	Right-angle		

Runway length = 9000 feet Airport elevation = 3,200 feet Design temperature = 80 deg. F. 90% dry pavement, 10% wet pavement

# Step by Step Instructions (7)

VirginiaTech

# Step by Step Instructions (8)

# Conclusions

- Airport is located at medium elevation
  - Higher approach speeds (result in longer landing roll out distance)
- Weighted average runway occupancy time is 60.2 seconds
  - Standard deviation of ROT is 13.2 seconds (high)
- High-speed runway exit "Charlie" is underused (16% of time)
- If this was a design exercise, we could move Charlie to 6,000 feet and Delta to 7,000 feet
  - Both acute angle exits could handle 42% and 33% of the traffic, respectively
  - Reduces ROT by a couple of seconds

## Another Example Runway Exit Improvements for PHL Airport Using the REDIM 4.0 Model

#### **Application of the Runway Exit Design Tool to PHL**

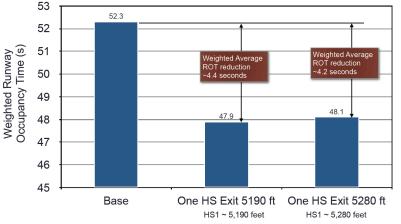

Runway Exit Study High-Speed Runway Exits at PHL Runway 27L	Scenario	Location of New Optimal High- Speed Exit (ft)	Wet/Dry Mix (%/%)	Remarks
	Baseline	Not applicable	10/90	Open exits: U, S7, Y, S9, S11, S12 and S13
N. Mirmohammadsadeghi, N. Hinze and A. Trani November 7, 2019	One High-Speed Runway Exit, 10/90	5,190	10/90	Open exits: U, S7, Y, NewHS1, S11, S12 and S13
	One High-Speed Runway Exit, 20/80	5,280	20/80	Open exits: U, S7, Y, NewHS1, S11, S12 and S13
Air Transportation Systems Laboratory				

- Runway exit Sierra-9 is eliminated
- **793 feet** distance between new exit high-speed exit HS2 and Sierra-11
   Optimally located runway exit in yellow

An Optimally Located High-Speed Runway Exit at PHL Runway 27L Could Reduce the Weighted Average Runway Occupancy Time by 4.4 to 4.2 Seconds

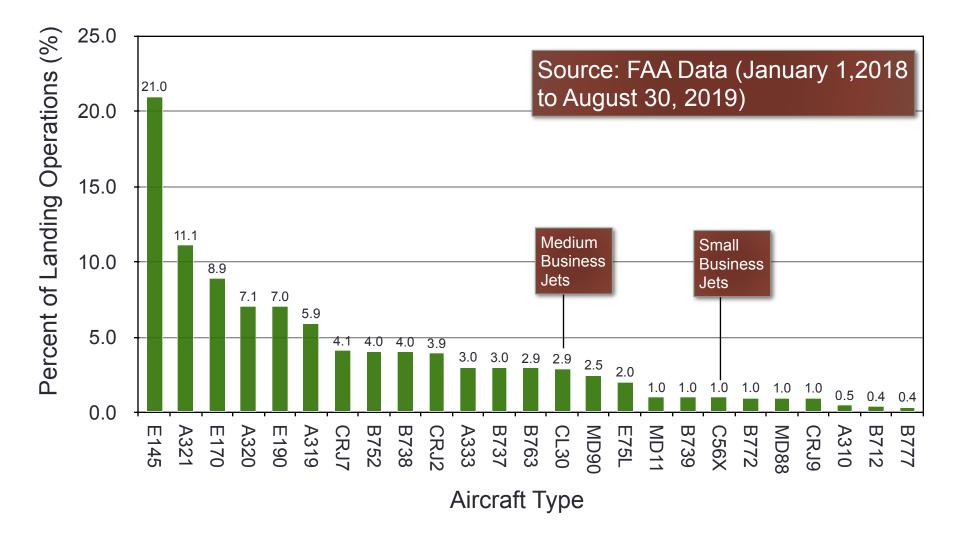

#### **Airport Fleet Mix Used in the Analysis of Runway 27L**

**Wirginia**Tech

Invent the Future

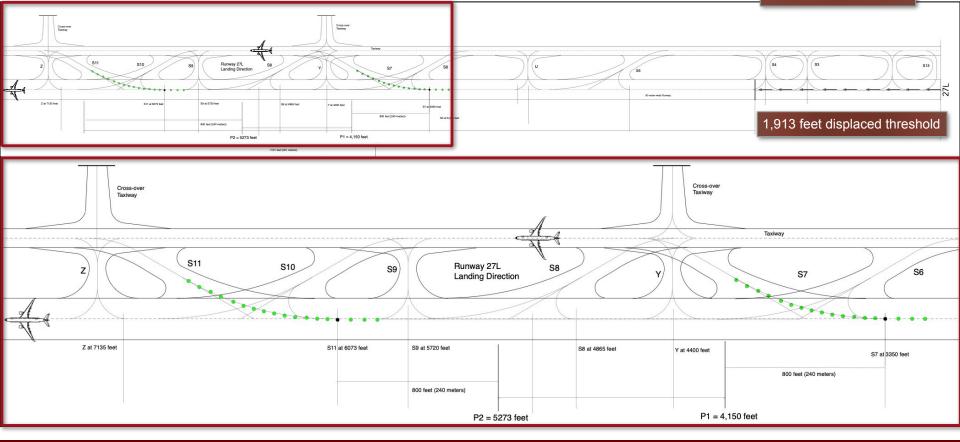

UirginiaTech

### PHL Runway 27L

- S7 located at 3,350 feet from threshold
- S11 located at 6,073 feet from threshold
- Earliest PC of new high-speed runway exit ~ 4150 feet
- Furthest PC of new high-speed runway exit ~ 5273 feet

If 800 feet is the minimum distance to locate two high-speed exits

## **Scenarios Studied with New PHL Fleet Mix**

Scenario	Location of New Optimal High- Speed Exit (ft)	Wet/Dry Mix (%/%)	Remarks
Baseline	Not applicable	10/90	<i>Open exits: U, S7, Y, S9, S11, S12 and S13</i>
One High-Speed Runway Exit, 10/90	5,190	10/90	<i>Open exits: U, S7, Y, NewHS1, S11, S12 and S13</i>
One High-Speed Runway Exit, 20/80	5,280	20/80	<i>Open exits: U, S7, Y, NewHS1, S11, S12 and S13</i>

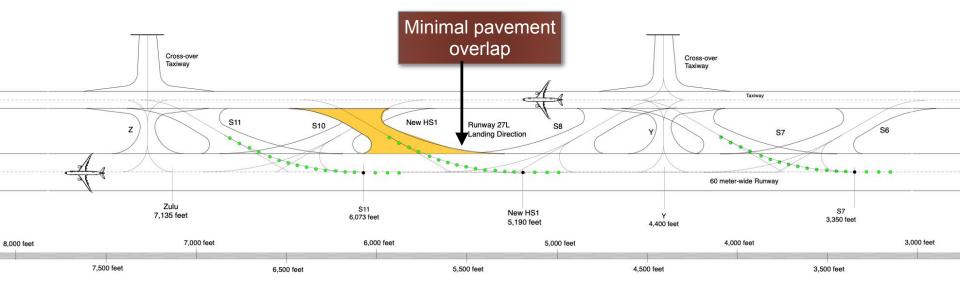

Optimal locations found using REDIM 3 dynamic programming algorithm The backup slides contain probabilities of precipitation at PHL

Case: One New High-Speed Runway Exit, 10/90 (wet/dry pavement design)

- Optimal location of a new High-Speed Runway exit designed for 10/90% wet/dry pavement conditions is <u>5,190</u> <u>feet</u> (point of curvature)
- Runway exit Sierra-9 is eliminated
- 883 feet distance between new exit high-speed exit HS1
   and Sierra-11
   Optimally located runway exit in yellow

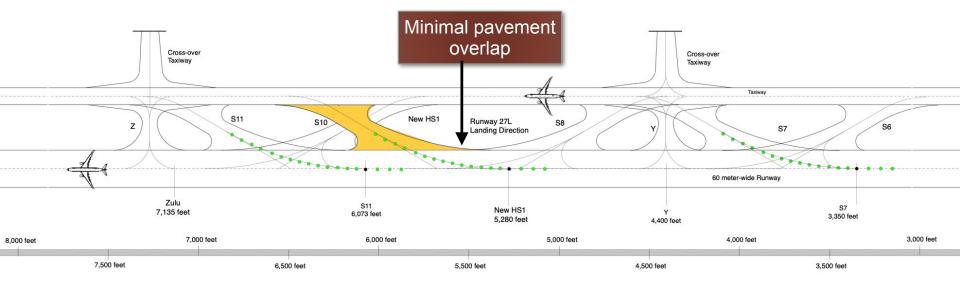

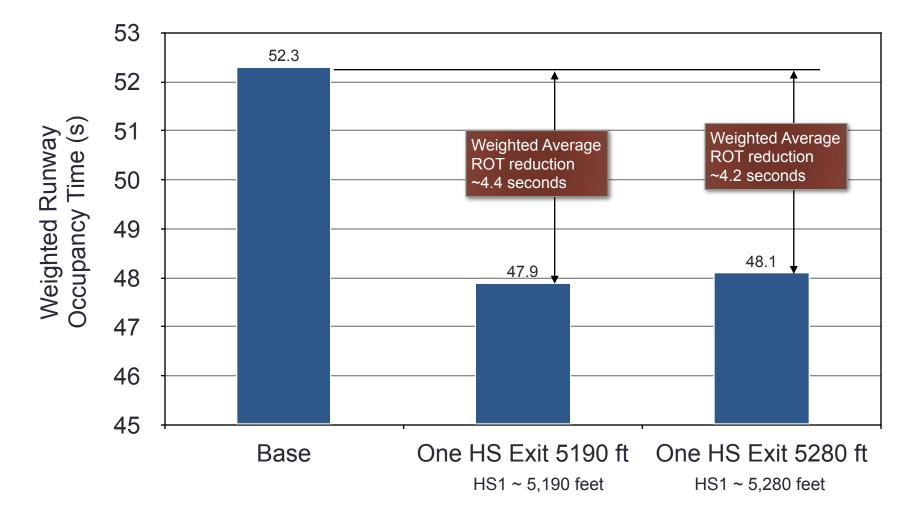

Case: One New High-Speed Runway Exit, 20/80 (wet/dry pavement design)

- Optimal location of a new High-Speed Runway exit designed for 20/80% wet/dry pavement conditions is <u>5,280</u> <u>feet</u> (point of curvature)
- Runway exit Sierra-9 is eliminated
- **793 feet** distance between new exit high-speed exit HS2 and Sierra-11 Optimally located runway exit in yellow

An Optimally Located High-Speed Runway Exit at PHL Runway 27L Could Reduce the Weighted Average Runway Occupancy Time by 4.4 to 4.2 Seconds

PHL Fleet Mix (Jan/2018 to Aug/2019) provided by FAA

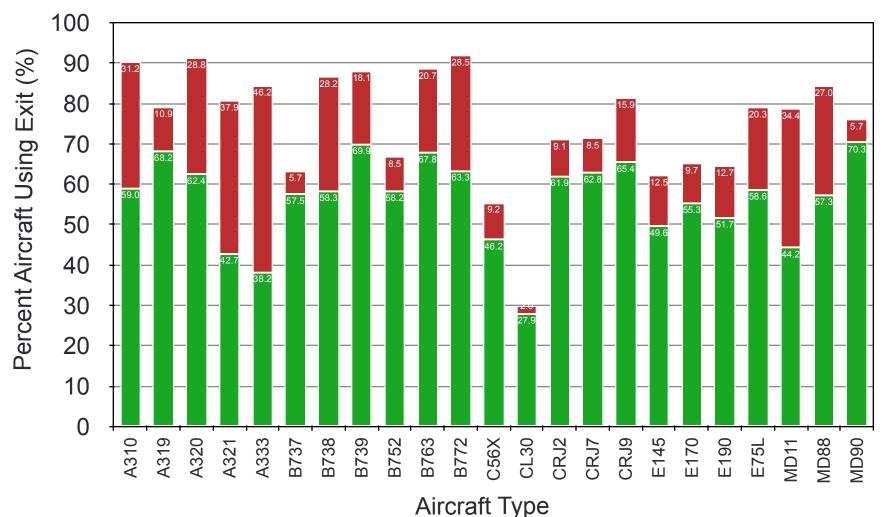

**WirginiaTech** 

Invent the Future

UirginiaTech

#### 54% of Landings on Runway 27L Could Use the New High-Speed Exit at 5,280 feet (20/80 wet/dry Design Scenario)

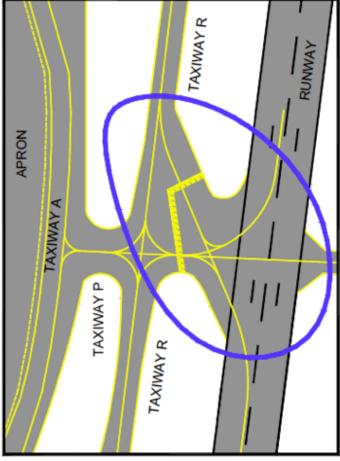

New HS Exit (5280 feet) High-Speed Exit Sierra 11 (6073 feet)

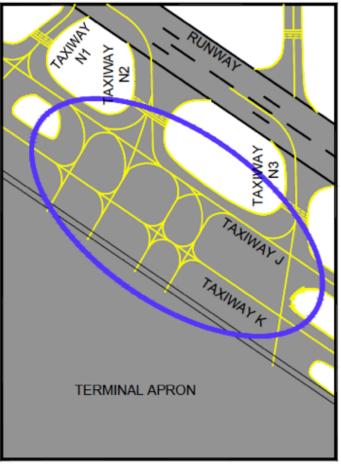

Air Transportation Systems Laboratory

## Other Runway Exit and Taxiway Considerations

# Things to Avoid (1)

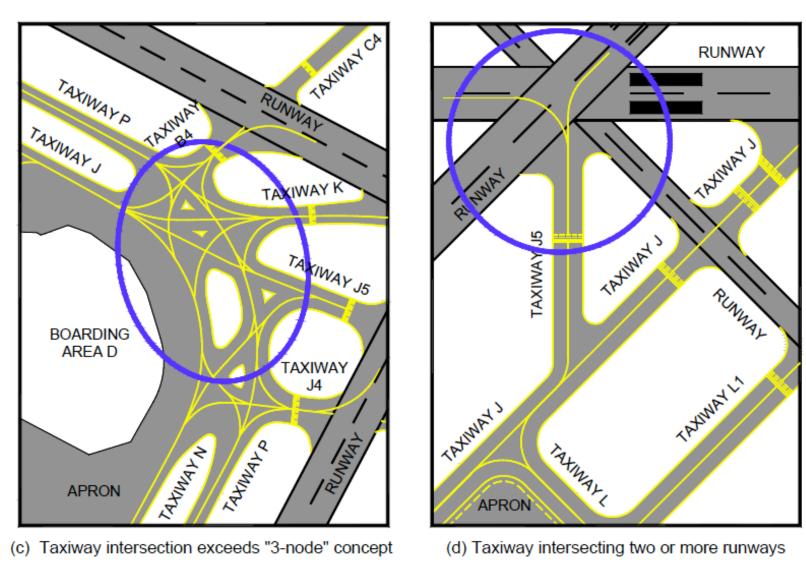

(a) Taxiway crossing high-speed exit and Wide throated runway entrance

(b) Extra-wide throated taxiway without "No Taxi" islands leading from the apron directly to parallel taxiways and runways

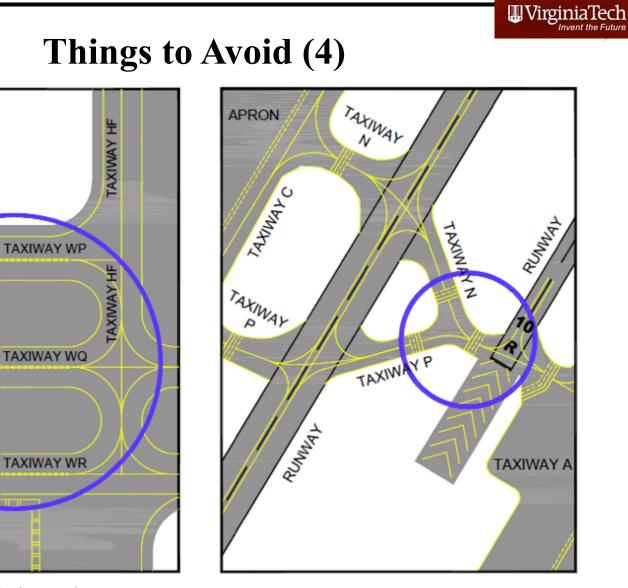

UirginiaTech

# Things to Avoid (2)

#### UirginiaTech Things to Avoid (3) TAXIWAY C-2 TAXIWAY C-3 TAXIWAY C-1 > RUNWAY **TAXIWAY D-2** TAXIWAY D RUNWAY TAXIWAY D TAXIWAY D TAXIMAY H

(e) Aligned taxiway between two closely spaced runway ends

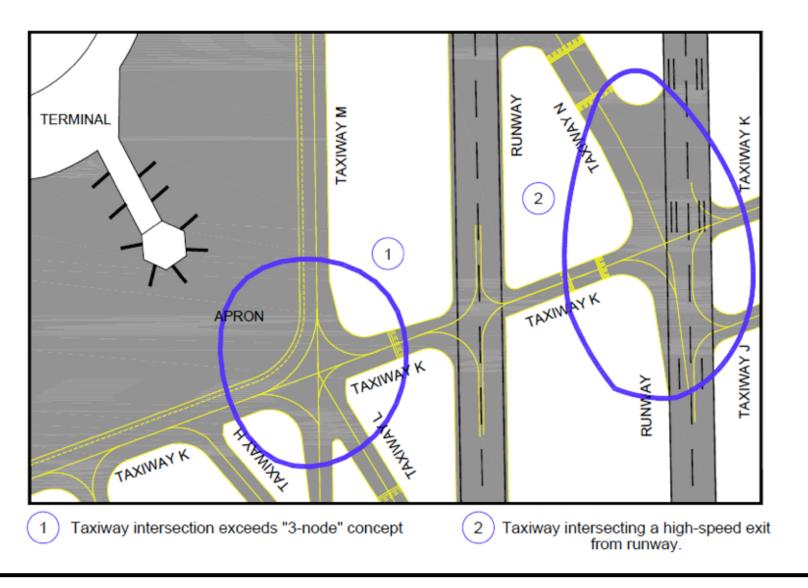

(f) Two or more taxiway entrances lacking "No Taxi" islands

RUNWAY

6

(g) "Y" Shaped taxiway crossing a runway

#### **Things to Avoid (5)**

UirginiaTech
